Assignment
Sorting & Filtering Data Using Power BI

Github Link : akashvenkey/Business-Analytics.3

A sales manager wants to identify the company's highest-value transactions and underperforming products. The main objective of this experiment is to use sorting and filtering techniques in Power BI Desktop to extract relevant business information from the given sales dataset. These techniques help organize sales data, identify high-value transactions, analyze product performance, and support effective business decision-making.

Steps Followed

Step 1: Data Import

- Opened Power BI Desktop.
- Imported the given Sales_Analysis_Dataset.pbix file.
- Examined the available sales data and report visuals.
- Identified the relevant fields required for sales and product analysis.

Step 2: Data Preparation

- Checked the data types of the relevant columns.
- Verified the sales values and product-related information.
- Ensured that the data was suitable for sorting and filtering.
- Selected the required fields for analysis.

Step 3: Sorting Data

- Selected the relevant table or visual in Power BI.
- Sorted the sales amount column in descending order to identify the highest-value transactions.
- Sorted the product sales values to compare product performance.
- Used ascending and descending sorting options to arrange the data according to the analysis requirements.

Step 4: Filtering Data

- Applied filters to display specific sales records.
- Used the sales amount field to focus on high-value transactions.

- Applied product-related filters to examine individual product performance.
- Used available slicers and filter options to narrow down the displayed information.
- Compared the filtered results to identify products with relatively low sales.

Step 5: Data Analysis

- Examined the highest-value transactions displayed after sorting.
- Compared sales values across different products.
- Identified products that required further performance analysis.
- Used the sorted and filtered results to understand sales performance and support business decisions.

Output

The sorting and filtering operations in Power BI help provide the following results:

- Identification of the highest-value sales transactions.
- Comparison of sales performance across products.
- Identification of relatively low-performing products.
- Easier analysis of selected sales records.
- Improved organization and interpretation of sales data.

Conclusion

This experiment demonstrates how sorting and filtering techniques in Power BI can be used to analyze sales data effectively. Sorting helps arrange transactions and product sales in the required order, while filtering allows the user to focus on specific records and categories. These techniques make it easier for a sales manager to identify high-value transactions, examine underperforming products, and make informed business decisions.

Business Insights

1. **Transaction Analysis:** Sorting sales values in descending order helps identify the highest-value transactions.
2. **Product Performance:** Comparing product sales helps distinguish products with higher and lower sales.
3. **Sales Monitoring:** Filtering enables focused analysis of selected transactions and products.
4. **Business Decision-Making:** The results help management identify areas that may require further investigation.

5. **Sales Improvement:** Analyzing underperforming products can support decisions related to inventory planning, marketing, and sales strategies.
